PROBLEM TO BE SOLVED: To provide a communication conference system with presence with simple constitution by providing a control means for setting the filter characteristic of a processing means processing a sound source signal and outputting right/left sound signals based on a setting value by means of a space information setting means setting space information in a virtual space.

SOLUTION: The sound signal of a speaker at a different place is transmitted and inputted to a sound input device 1. A conference room information setting means 2 selects and inputs a prescribed pattern from storage information and sets seat position information of the respective speakers. The processing means 4 processes the sound signal of the speaker from the sound input device 1, corrects the sound source signal by the filter characteristic and outputs the right/left sound signals. The control means 5 decides the filter characteristic of the processing means 4 for the respective sound signals of the respective speakers based on seat position information of the respective speakers, which are set by the conference room information setting means 2 and stored in the storage means 3, and outputs a

coefficient. Address 6 and 7 respectively output the right/left sound signals to the right/left speakers 8 and 9 based on the outputs of the processing means.
